

Built to support choice

TEXT CHAT

LIVE VOICE

Talk Live screen in the app's preview mode (no live audio). When the goal is reached, the call says so and lets you hang up or keep talking.

Challenges I ran into

The hardest design challenge was giving people control. Feedback shaped a space where users could try different replies, ask for help, and reflect without a grade.

Trust mattered too. NEXUS explains its purpose up front to address worries about AI and judgment. To ask communities for feedback respectfully, I learned each server's rules and requested permission before posting.

Testing found bugs too. Larger text pushed the chat off screen, and the Narrator never stepped in when replies got short. Both were fixed and rechecked by replaying the same steps.

Fixes: commits 43f2ad6 and f824789. Automated browser checks also caught a blank-screen crash before launch.

What I'm proud of

I'm most proud that neurodivergent users helped shape NEXUS. Their input guided a practice space that brings together scripted scenarios, AI roleplay, and live voice while supporting different ways to participate. Building NEXUS taught me that accessibility starts with listening and grows through feedback, testing, and revision.

I used AI coding assistants to help write and test code from my specifications. I made the design decisions and tested each version, taking responsibility for how the experience worked.

How the code is organized

- Scan for the code and development log
- React client and Express server, deployed on Railway
- Scenarios and characters stored as JSON data
- API key on the server; rate limits guard the demo
